(54) Multi-size reel symbols

(57) Slot machine display reels are provided with a plurality of symbols 13 occupying differing proportions of the circumference of the reel, such that those symbols which require greater prominance, such as a jackpot, occupy a larger proportion of the circumference. Associated with each reel is a spinning mechanism, such as stopper motor 11, which is able to position any symbol on the reel centrally within an associated display window, irrespective of the size of that symbol, by taking the size of the respective symbol into account when determining the stopping position.

- 100 RANDOM NUMBER GENERATOR CHOOSES SYMBOL NUMBER TO BE DISPLAYED ON REEL. -110 LOOK UP TABLE TO DETERMINE THE NUMBER OF MOTOR PULSES REQUIRED TO STOP THE REEL FROM THE INDEX POSITION TO THE CHOSEN SYMBOL POSITION. - 120 STEP REEL TO THE INDEX POSITION AFTER A SUITABLE NUMBER OF REVOLUTIONS AND STEP THE NUMBER OF STEPS DETERMINED BY THE LOOK UP TABLE. FIG.5

: 75

FIG.11

65

SPECIFICATION

	Multi-size reel symbols	
5	The present invention relates to gaming machines of the type known as poker machines, fruit machines or slot machines and in particular the invention relates to improvements in poker machine display reels.	5
10	Historically, symbols on a particular sized poker machine reel have always been identical in height, or more specifically the space allocated to each symbol has been equal, irrespective of the size of the symbol contained thereon. For example, the area allocated for an "orange" symbol is the same size as that for a "bar" symbol even though the picture for the bar symbol is not as high as that for the orange. In the past, the space allocated to each symbol, which is generally referred to as a "card", has been a function of the number of stops on the reel and	10
15	the provision of equal spacing for each symbol has been dictated by the mechanical nature of the reel stopping mechanism. Further it has been the practice in the past to allocate one symbol for each stopping position of the reel. However, this limitation does not apply to stepper motor driven machines where the final reel position is predetermined before the spinning of the reel and where the stepping motor is able to step the reel in increments which are substantially	15
20	smaller than the height allocated to each reel symbol. Also, the possibility exists in conventional machines to include symbols which occupy a space which is a multiple of the prior art symbol space or card.	20
25	The present invention consists in a reel for a poker machine display, said reel including a cylindrical peripheral surface to which a plurality of indicia are applied, each of said indicia having a symbol space within which the indicia is substantially centrally located, said symbol space occupying a proportion of the circumference of the cylindrical surface which is different for different indicia on said surface.	25
30	The provision of symbols of different sizes around the periphery of the poker machine reel allows the use of larger indicia for those reel positions which feature in larger pay outs, thereby making it easier for the player to recognise those symbols. In the case of stepping motor driven machines, the provision of indicia of different sizes also	30
	has the additional advantage that it allows the implementation of poker machine reels on which the number of indicia is not an integral sub-multiple of the number of pulses required to step through a full revolution. For example, a stepping motor which is typically used to drive a poker machine reel will be driven through one revolution by applying 200 pulses to the motor.	
35	Therefore, if the reel is provided with 25 indicia, 8 pulses are required to step the reel by one symbol position, however, if all symbols were spaced by an equal number of pulses, it would not be possible to produce reels having 21, 22 or 23 symbols. In contrast, poker machine reels	35
40	made in accordance with the present invention may have any number of symbols and the number of motor pulses associated with each symbol may be adjusted in relation to the height of the symbol, with the total for one revolution of the reel still adding up to 200 pulses. The invention is of particular advantage in the United States where machines known as "Keno" type machines have only a few symbols spaced around the periphery of their reels with	40
45	the remainder of the reels being blank. In such machines the symbol positions upon which the reel stops, after it is rotated, may be unevenly spaced such that the stopping positions either side of the symbol position are spaced further from the symbol position than are adjacent stopping positions associated with blank portions of the reel. The present invention permits the area occupied by the symbols on the Keno reel (typically "bar" symbols) to be two or three	45
50	times their present size with the intervening blanks correspondingly smaller. As it is usual to have several blank symbols joining each other between each bar symbol, and as there is usually no dividing line between adjacent symbols, it would not be obvious, to players of the machine that the different symbols were allocated different proportions of the circumference of the reel and therefore the invention would not provide any visually disturbing	50
55	effect when applied to Keno machines. Further, any apparent abnormality in the display when applied to normal poker machines would also be minimal. Stepping motor driven poker machines using a 200 pulse per revolution motor, and equipped with reels in accordance with the present invention, can be operated with 20, 21, 22, 23 or	55
60	even 26 symbol reels instead of the typical 25 symbol reels presently used. In some cases, where a large symbol is displayed in the position adjacent to the centre-line, some proportion of that symbol may be obscured from view if the player does not adjust his viewing position, however, this is not considered to be a significant disadvantage. Also, in those cases where the symbol adjacent to the symbol of the centre-line is smaller than the nominal symbol height, a small portion of the next symbol may also be visible.	60

symbol height, a small portion of the next symbol may also be visible.

Embodiments of the invention will now be described, by way of example, with reference to the accompanying drawings in which:
Fig. 1 illustrates a typical prior art machine having 25 equally sized symbol spaces;

Finally, in the motor is controlled to first provide a number of steps the reel and then finally to step to the index position and execute a number of revolutions of the reel and then finally to step to the index position and execute a number of revolutions of the reel and then finally to step to the stepping on from the index position by a number of steps equal to the symbol number multiplea 45 by the number of steps per symbol. 46 Referring to Figs. 6-10, conventional poker machines with	30	simple modification to the typical control scheme is all that is required in order to accommodate reels in accordance with the present invention. Referring to Fig. 5, a portion of a flow chart describing the control programme of a poker machine, in which the dashed arrows represent portions of an existing poker machine control										
the number of motor pulses required to step the reel from the index position to the selected symbol. Finally, in the motor control portion of the poker machine control programme, the motor is controlled to first provide a number of revolutions of the reel and then finally to step to the index position and execute a number of steps equal to the number looked up in the look up table. This programme step indicated as item 120 would replace the prior art procedure of stepping on from the index position by a number of steps equal to the symbol number multiplied by the number of steps per symbol. Referring to Figs. 6-10, conventional poker machines with the free spinning reels are generally provided with stopping mechanisms which allow the reels to be stopped at half card or full card intervals, where a card 30 is the standard division of the circumference of the reel and typically there are 25 cards to a reel. In such machines it is possible to implement the present invention by using symbol areas which are multiples (eg. 2x or 3x) the standard card such as with the "JACKPOT" symbol 31 of Figs. 6, 7 and 8. When multiple card symbols 31 are used, however, it becomes necessary to test the reel when stopped, to determine whether a large card is in the centre line 32 of the window 33 and if so whether it is centred on the centre line 32. In the case of a double sized card 31, as illustrated in Figs. 6, 7 and 8, it will be necessary to nudge the card forward or backward by half a card, if the large symbol is not centred on the centre line 32. The technique of nudging is well known and understood and a variety of prior art machines have been produced in which the reels could be nudged forward or backward by one or more positions, for various purposes, and an explanation of the mechanism used will not be given here. Referring to Fig. 9, centering of the double sized symbol of Figs. 6-8 is achieved by first testing (200) to see if the reel has stopped on the first half of the double sized card, the programme would then t	35	tion in th with	of a symbone control protection the present	l upo rogra t inve	on whome mme entior mach	hich the par of many p n, an addition nine, the ste	ticuli oker onal op 1	ar reel machi step 1 10 bei	is to be stopped, this being a pre-existing step nes. card, before continuing (220) with the standard procedure. Alternatively, if the reel had not stopped on either half of the double sized card, the programme would simply continue (220) with its standard procedure.

It is also possible to use reel strips using triple sized symbols (not shown), in which case it will be necessary under some circumstances to nudge the reel forward or backward by a full card position. Referring to Fig. 10, the flow chart for a symbol centering routine for a machine with a triple sized symbol is illustrated, from which it will be seen that once the reel has stopped spinning, the reel is tested (300) to determine whether it has stopped with the central portion of the triple sized symbol on the centre line, in which case standard processing will be continued (310). If the reel had not stopped on the central portion of the large symbol, a test is performed (320) to determine whether the reel has stopped on the first portion of the large symbol, in which case the reel will be nudged upward (330) by one card and standard processing continued (310). Finally, if the reel has not stopped on the third card of the large symbol in which case the reel will nudge downward (350) by one card before standard processing is continued (310). Alternatively, if the reel has not stopped with any cards of the triple sized symbol on the centre line, no nudging will take place and standard processing will continue (310).

It will be recognised by persons skilled in the art that numerous variations and modifications 20 may be made to the invention as described above without departing from the spirit or scope of the invention as broadly described.

CLAIMS

- 1. A reel for a poker machine display, said reel including a cylindrical peripheral surface to 25 which a plurality of indicia are applied, each of said indicia having a symbol space within which the indicia is substantially centrally located, said symbol spaces occupying a proportion of the circumference of the cylindrical surface which is different for different indicia on said surface.
- The reel as claimed in claim 1 wherein a majority of the indicia on said reel have symbol spaces of uniform size and the remainder of the indicia have a symbol space which differs from 30 the uniform size by an amount which is a fraction of the uniform size.
 - 3. The reel as claimed in claim 1 wherein a majority of the indicia on said reel have symbol spaces of uniform size and the remainder of the indicia have a symbol space which is an integer multiple of the uniform size.
- 4. A poker machine including one or more reels as claimed in claim 1, 2 or 3, each of said 35 reels being driven by a stepping motor and each of the symbol spaces occupying a proportion of the circumference of the reel which is a multiple of the incremental rotational step size of its respective stepping motor.
- 5. The poker machine of claim 4 wherein a look up table is provided in which are stored the number of motor steps corresponding to each symbol space on the reels, the look up table 40 being used to calculate the correct number of steps required to stop a reel with any given symbol centered on a display centre line.
- 6. A poker machine including one or more reels as claimed in claim 1 or 3, the machine being provided with nudging means for nudging a reel forward or backward by an amount necessary to centre one of said remainder of the indicia on a display centre line when the respective indicia 45 has come to rest on said centre line without being centered thereon.
